Nexant

The contributions of the RBSA advisory groups were essential to designing and planning another successful RBSA

efficiency organizations working to accelerate the innovation and adoption of energy-efficient products, services and practices in the Northwest.

Many thanks to all of the Northwest utilities that participated in the quarterly meetings, provided billing data, and contributed suggestions About this Study

Primary Objective

Key Findings

The Northwest Energy Efficiency Alliance (NEEA) completed its second Residential Building Stock Assessment (RBSA) in the fall of 2017. The RBSA is a broad, regional study that characterizes the building stock within three housing types: single-family homes, manufactured homes, and multifamily buildings. This is NEEA's second residential building stock assessment since its first comprehensive, regionally representative study in the 2011-2012 timeframe. For this study, NEEA continued the work of the first RBSA (referred to as RBSA I in this report) and, wherever possible, data were collected in a similar manner to ensure continuity and comparability between the studies. Cadmus conducted the second RBSA (referred to as RBSA II in this report) and collected data in the 2016-2017 timeframe, with recruiting support from Nexant.

The primary objective of the RBSA is to characterize the existing residential building stock in the Northwest region based on data from a representative sample of homes. NEEA and its partners designed the RBSA to account for regional differences, such as climate, building practices, and fuel choices, by using a large-scale residential sample. The characterization includes the principal characteristics of the homes (e.g., square footage, insulation level, and heating systems), their occupants (e.g., household size and income levels), and their end-use equipment (e.g., lighting, appliances, electronics, and water heating). The sample size chosen for the RBSA II allows benchmarking of energy use within households at sufficient detail to assess the progress of changes in energy efficiency and home characteristics within the region.

Executive Summary

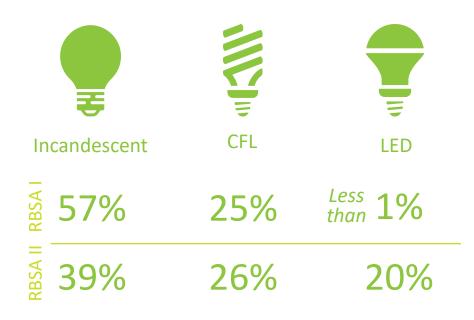

This report presents findings for single-family homes, based on data collected from 1,100 site visits, which includes the core RBSA study (funded by NEEA), as well as data collected for three oversamples funded by Bonneville Power Administration (BPA), Seattle City Light, and Snohomish Public Utility District (PUD). Cadmus developed and applied sampling weights to ensure that all single-family home observations were weighted proportionally to the segment of the population represented by the sample; see Database User Manual for a description of the weighting methods and procedures.

The following section presents the study's key findings by end use or measurement. All values in this section are weighted. These key findings represent notable and statistically significant differences between the RBSA I and RBSA II, and in some cases, the emergence of new or different technologies that were not observed in RBSA I.

Lighting

LED adoption has soared

The data from this study reveal a dramatic shift in the efficiency of residential lighting. LEDs have increased from less than one percent six years ago to nearly a quarter of all installed bulbs, with LEDs found in rooms of every type. The percentage of installed incandescent bulbs greatly declined, while CFLs remained relatively flat.

More homes are using gas equipment and appliances

Gas fuel shares for primary heating systems, water heaters, stoves, and ovens have increased, while the share of other fuel types, such as electric, have decreased.

RBSA |

RBSA II

Connected devices have emerged in homes

Though found in only a small percentage of homes, connected lighting products have emerged since RBSA I, largely without program support. Wi-Fi and smart thermostats, which have been rebated through regional programs for several years, were also observed in this RBSA study.

Electric heating and cooling equipment are more efficient

The efficiency of heat pumps and central air conditioners increased relative to the previous RBSA study. Gas furnace efficiencies also increased.

RBSA Overview

About this Report

This report includes key findings and themes from the RBSA II, organized by building component and end-use equipment. Each report section provides a high-level summary of data collection protocols, procedures, and findings. Where practical, these sections also highlight key differences between the RBSA II and RBSA I. Cadmus used two-sided t-tests for means and proportions to test the hypotheses that the current RBSA results were equal or not equal to the RBSA I results. We identified metrics where significant changes have occurred over time when tests resulted in p-values of p<0.01 and this is denoted by either \blacktriangle or \triangledown symbol, to indicate whether the value is higher or lower than in the previous study. We did not account for uncertainty of the RBSA I results and treated them as fixed values. Appendix A provides additional detail and supplemental data tables.

To streamline the results, the report includes only a snapshot of the collected and analyzed data. Readers may select the **SEE THE DATA button** (presented throughout the report) to view the detailed tables in the appendix. These tables provide all weighted single-family data from the study, with sample sizes and error bounds. In some instances, Cadmus rounded values to whole numbers for better readability. In these instances, values may not sum exactly to 100%.

The RBSA II database contains additional data, including the full data from the inventory of each home. For more details regarding the database go to neea.org/data or www.NEEA.org.

Facilitation of Working Group Sessions and Production Pretest

The RBSA provides data vital for planning and evaluation at the regional, state, and local utility levels. As such, NEEA engaged regional stakeholders in the study design and planning. Cadmus facilitated 10 working group sessions with NEEA funders and other regional stakeholders, including sessions focused on customer contact, sample design, data collection, and database development.

These sessions provided a mechanism for NEEA, Cadmus, and regional stakeholders to review and provide feedback on the proposed methods and activities planned for the RBSA II. Following the working groups, Cadmus delivered a set of interim protocols documenting the agreed-upon approach for all aspects of the RBSA data collection process such as procedures for customer engagement and interactions, the sample design, and the data points collected as part of the RBSA.

As agreed upon with NEEA, the team pretested the recruiting and data collection protocols developed during the working group sessions to ensure that the processes and tools operated as designed. During the pretest period in February 2016, the Cadmus team identified and recommended a number of small changes to improve the recruitment and data collection processes. Over the course of the study, the team made minor adjustments to the original plan, with most changes aimed at improving the recruitment process.

Implementing the RBSA II

The RBSA data collection effort included recruiting and surveying participants, acquiring signed billing release forms, and collecting data on observed equipment and home characteristics. Field technicians recorded observed information on nearly every characteristic that impacts the energy consumption of the home—from construction details to the wattage of light bulbs. The field team implemented lessons learned from the previous RBSA to improve data collection and measurements. These differences are called out throughout the report where applicable.

Customer Survey

Participants completed two short surveys about their home and its occupants: one as a part of a screening and opt-in process and another as part of the site visit. The in-home survey also collected information to help field technicians identify unusual types of equipment they should look for during the site visit such as Wi-Fi enabled equipment, electric vehicles, or seasonal heating and cooling equipment that may be kept in storage.

As the final step of the on-site interview, field technicians recorded the customer's utility (electric and gas) and utility account information and had the customer electronically sign a billing release form.

Observed Equipment and Home Characteristics

The RBSA on-site data collection was wide-ranging and, while the data collected varied based on the type of equipment in the home, generally included these observations:

- Building configuration: foundation type, number of floors, room square footage, and conditioned area and volume
- Building envelope (shell): window characteristics, insulation types and thicknesses, and construction materials
- Air leakage: air leakage in cubic feet per minute at 50 pascals, as measured by a blower door test
- HVAC: equipment characteristics, nameplate information, location, and TrueFlow[®] air handler flow testing and pressure measurements for electric central forced air heating systems
- Domestic hot water: equipment characteristics, nameplate information, and flow rate measurements for shower heads and faucets
- Appliances: equipment characteristics (size and configuration) and nameplate information
- Electronics: equipment characteristics and nameplate information
- Lighting: type, style, wattage, quantity, control type, and location

A comprehensive list of the types of equipment information field technicians collected by equipment category and home type and specific details for how field technicians collected data and tested home performance can be found at neea.org/data or go to www.NEEA.org.

This is NEEA's second comprehensive singlefamily building stock assessment.

NEEA conducted 10 working group sessions.

Observed Equipment

Home Diagnostic Testing

Through the working groups, Cadmus and NEEA learned that regional stakeholders desired more comprehensive information about whole-home air leakage and HVAC airflow. As such, field technicians performed blowerdoor testing on all single-family homes in the study sample where they could run the test safely, without detracting from participant satisfaction. They also conducted TrueFlow testing and gathered pressure data for households with an electric central forced-air furnace or heat pump as the primary heating system.

A blower-door test measures the amount of air leakage (or air tightness) of a structure, which is a primary determinant of thermal energy efficiency. Air leakage can also affect occupant comfort, indoor air quality, and building durability. Field technicians conducted a two-point blower-door test, striking a balance between the expediency of single-point testing and the greater reliability and accuracy of multipoint testing.

Where practical, field technicians used the TrueFlow Air Handler Flow Meter to collect data and calculate airflow across air handlers in electric central HVAC systems such as furnaces and heat pumps. Considered with other information, such as the condition of the filter and the type and capacity of the current heating system, this data can help assess the adequacy of the duct system for the current system and/or an air source heat pump.

Data Cleaning and Building and Equipment Characteristic Analysis

Throughout the field data collection process, Cadmus performed continuous quality assurance (QA) reviews on data collected for randomly selected homes. The QA reviews focused on critical equipment categories, such as lighting and building construction, and emphasized identifying missing, incomplete, or inconsistent data (i.e., building construction attributes that were inconsistent with the other home characteristics). Where applicable, Cadmus updated data points based on data collection notes, photographs, or product lookup and provided feedback to its technicians to improve data collection.

After completing the site visits, Cadmus cleaned and analyzed the data. This process included reviewing the data for outliers, using field notes and photographs to determine whether a change to a data point was required, and correcting data where appropriate. The final data review also included a systematic review of each home and its equipment to ensure internal consistency. For example, Cadmus compared the type of wall framing to the age of home and reported R-value. If there was a discrepancy between these values, the team investigated the issue further and made appropriate changes if required.

The analysis relied on R statistical software to process, compile tables, and apply case weights to estimate population means and proportions as well as their error bounds. Each end-use table and reported statistic includes data on the associated population estimates and their error bounds (calculated at 90% confidence).

Billing Data Collection and Analysis

Cadmus conducted interviews to capture participant electric and gas billing information such as utility, account number, and meter numbers. Near the end of the field collection phase, Cadmus requested up to 24 months of participant billing data from utilities and reviewed them for completeness and to ensure Cadmus received data for every site, following up directly with utilities for clarification as necessary.

Cadmus performed the following checks to assess the quality of the billing data:

- Reviewed the premise address and accounts for each requested site to ensure they matched those in our database.
- Reviewed the data for inconsistencies such as duplicate reads, multiple readings on the same date, and missing data.
- Reviewed plots of each site's usage data to identify anomalies in the data, such as vacancies or erroneous readings, and removing the consumption data or further investigating the sites as needed.

Cadmus investigated anomalous data and, if possible, corrected the issue. If unable to correct the issue, Cadmus removed the customer from the energy use intensity (EUI) analysis .

The billing analysis relied on a PRISM-type variable-based degree day model. Cadmus used this model to process each home's monthly billing data to produce weather-adjusted annual consumption values. For each household, Cadmus modeled energy usage as a function of heating degree days and cooling degree days, collected from the nearest NOAA weather station. This allowed Cadmus to disaggregate energy into heating, cooling, and baseload components and then apply typical meteorological year (TMY)3 data to these components to derive a normalized annual usage for each household. Finally, to calculate a home's EUI, Cadmus divided the household's normalized usage by the home's conditioned living area.

Database

Results for the RBSA II are derived from data collected through participant surveys, on-site data collection by trained technicians, and historical energy consumption data furnished by regional utilities. Cadmus cleaned, anonymized, and compiled these data, including a number of calculated fields, into a publicly available database. The database includes data from all three housing types single-family, multifamily, and manufactured—and is available for download through the NEEA website. The RBSA database is a relational database provided in CSV format. Users can import the flat files into other database software (i.e., Access or SQL) or spreadsheet programs such as Excel.

Cadmus also developed a database user manual and data dictionary. The user manual provides guidance on how to effectively use the database and includes instructions for incorporating sampling weights. The data dictionary defines each field in the database and provides example data for each field to give the end user a better idea of what the data mean and represent.

The database and associated documents are available at neea.org/data or go to www.NEEA.org.

Field technicians conducted wholehome air leakage and HVAC airflow testing.

Cadmus collected homeowner billing consumption data to develop an energy use intensity (EUI) for each home.

The RBSA II database contains complete data from the inventory of each home.

Sampling

Background

Cadmus designed the single-family home sample to achieve the desired level of confidence and precision (90% confidence with ±10% precision) for population estimates within each of seven geographic sub-regions. The sampling plan was designed so that these targets and the requisite sample sizes would be met wholly through NEEA project funding. Although NEEA expected some utilities and regional organizations to fund oversamples for their individual service territories, the core sample design accepted by NEEA did not rely on oversamples to meet the desired confidence and precision. This is a key difference between the current study and the previous RBSA; that is, the RBSA I did incorporate an oversample (the BPA oversample) into the core sample design; this study did not.

The following sections describe Cadmus's approach to developing the sample frame, determining the sample sizes for the core and the oversamples, and estimating population quantities using post-stratification to incorporate data from the core and oversamples.

Sample Frame Development

The goal of the single-family home sample design was to draw samples that were representative of the population within the following seven geographic sub-regions:

- Western Washington Idaho
- Western Montana
- Puget Sound
- Eastern Washington Western Oregon
- Eastern Oregon

To ensure that the sample was representative of the target population within each region, Cadmus purchased a randomized address-based sample generated by the U.S. Postal Service (USPS) within each geographic subregion. Cadmus provided USPS with a list of counties and the number of residences required to reach the sample size targets in each geographic region. After identifying the total number of homes in each zip code that were proportional to the population of homes in the region, Cadmus requested those amounts from USPS. That is, if one county represented 50% of the total regional home population, approximately 50% of the addressbased sample would be from that county.

Core Sample Sizes

Cadmus determined the sample sizes within each geographic sub-region for the core sample. The team calculated the target sample size within each subregion and then combined them to determine the sample size for the entire region.

Table 1 lists the target and achieved sample sizes for the RBSA II single-family core sample by sub-region.

Table 1. Target and Achieved Sample Sizes

| | Single-Fa | mily Homes |
|--------------------|-----------|------------|
| Sub-Region | Target | Achieved |
| Western Montana | 107 | 111 |
| Idaho | 107 | 107 |
| Puget Sound | 107 | 111 |
| Western Washington | 107 | 107 |
| Eastern Washington | 107 | 108 |
| Eastern Oregon | 107 | 107 |
| Western Oregon | 107 | 110 |
| Total | 749 | 761 |

Utility and BPA Oversample Sample Sizes

Seattle City Light, Snohomish PUD, and BPA requested oversamples in their service territories to include additional single-family homes. The Cadmus team calculated the sample sizes for the oversample using the same equation as used for the core sample, with inputs specific to each utility and BPA. Based on the population of homes served by each utility and BPA, relative to the population in the region, Cadmus predicted the number of homes that would eventually be included in the core sample from each oversample region and reduced the total oversample sample size by that amount. Table 2 shows resulting oversample sample sizes for each utility and BPA.

Table 2. Utility Oversample Sample Sizes

| Sub-Region | Seattle City Light | Snohomish County PUD | BPA |
|---------------------------------------|-----------------------|-------------------------|-----|
| Western Montana/ Idaho | | | 32 |
| Puget Sound | 139 | 31 | 49 |
| Western Washington | | | 10 |
| Eastern Washington/ Eastern Oregon | | | 18 |
| Western Oregon | | | 60 |
| Totals | 139 | 31 | 169 |

The goal of the singlefamily home sample design was to draw samples that were representative of the population within seven sub-regions.

Sampling Weights

Cadmus used stratified sampling to select households for the core sample where strata were defined by geographic sub-regions. Cadmus calculated and applied sampling weights to estimate the overall population quantities and ensure that observations are weighted in proportion to the population represented by the sample. The oversamples introduced additional sampling within each core stratum and, thereby, the need for an adjustment to the core stratified sampling weights to account for sample size increases in the oversampled territories.

Cadmus used post-stratification to account for the combination of stratified sampling in the core and the additional sampling in the oversamples. To poststratify, Cadmus divided the Puget Sound sub-region into BPA, Snohomish PUD, and Seattle City Light territories and divided the other sub-regions into BPA and non-BPA territories. Cadmus determined the population sizes in each post-stratification stratum based on home data from the 2014 American Community Survey (ACS) and achieved sample sizes.

The Cadmus team mapped home population sizes from the ACS data to the zip codes in each sub-region and service territory to determine stratum population sizes and counted the achieved sample sizes in each stratum. The team applied sampling weights to all observations within each stratum to estimate population totals, means, and proportions.

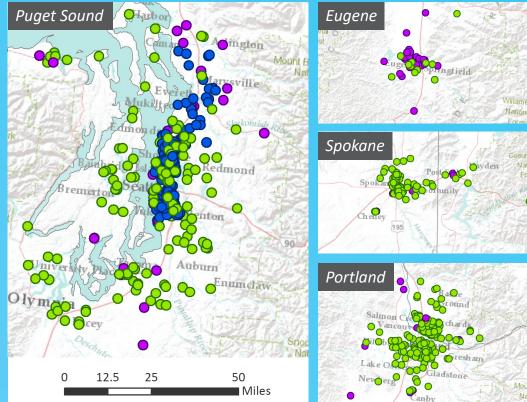

Table 3 lists the post-stratification strata within each sub-region.

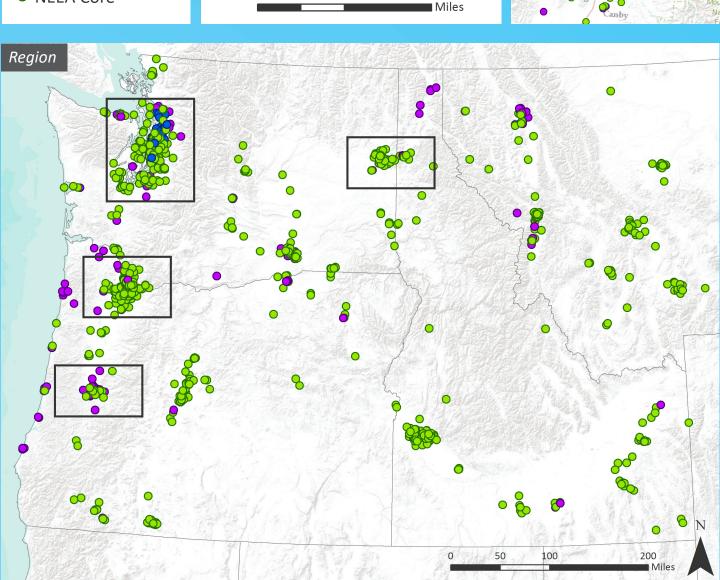

Table 3. Post-Stratification by Sub-Region

| Sub-Region | Post-Stratification Strata |

The following maps show the distribution of singlefamily site visits across Idaho, Western Montana, Oregon, and Washington by NEEA's core RBSA II sample, as well as utility and BPA oversample homes. The maps also show a more detailed breakout of site visits for these areas: Puget Sound, Portland, Eugene, and Spokane.

Utility OversampleBPA OversampleNEEA Core

SUMMARY OF BUILDING CHARACTERISTICS

The following sections provide detailed findings by home characteristic, measurement, and end use. All values in these sections are weighted. These findings represent notable and statistically significant differences between the RBSA II and the previous RBSA, and in some situations, the emergence of new or different technologies not observed in RBSA I.

Where practical, these sections also highlight key differences between the RBSA II and RBSA I. Differences that are statistically significant are denoted by either an ▲ or ▼ symbol, to indicate whether the value is higher or lower than in the previous study. Where Cadmus observed new or different technologies, or if we developed tables for this RBSA that were not present in the RBSA I, we did not conduct statistical significance testing.

Appendix A provides additional detail and supplemental data tables, as well as references to comparable RBSA I table numbers.

This page intentionally left blank.

Age and Type

Description

Key Findings

The RBSA II defined single-family homes according to the Northwest Power and Conservation Council's definition: individual residences in buildings with fewer than five residential units in a single structure. Single-family building types include detached single-family, townhouse or rowhouse, duplex, triplex, and fourplex.

A detached single-family home does not share a common wall with an adjacent unit or structure. A townhouse or rowhouse abuts one or more buildings, does not sit even partially above or below a separate living unit, and rests on land owned by the owner of the home. A duplex, triplex, and fourplex may include shared floors or ceilings. When Cadmus recruited one unit within a duplex, triplex, or fourplex, field technicians only recorded information for the recruited unit.

Cadmus identified the age of the home first by asking the participant and then verifying through online sources.

Key findings for home type and vintage include:

- Consistent with the previous RBSA, just under a quarter of the sample comprises homes built prior to 1951 that have only undergone modest additions in subsequent decades.
- Two decades stand out where new housing stock spiked (1970s and early 2000s), and these spikes are consistent for all states. The spikes are most pronounced in Idaho and Montana, with Idaho experiencing the largest housing stock increases across the region per decade . There is a noticeable decline in new housing stock after 2010, but these data represent only seven years.
- Cadmus conducted 87% of RBSA II site visits in single-family detached homes, which is a 6% decline from the previous RBSA. There was an increase in site visits to duplex, triplex, and fourplex homes for all states and decreased site visits to town and rowhomes in Idaho.
- Cadmus compared collected building stock data with applicable home characteristics from the American Community Survey (ACS) to ensure that the study results were representative of the population reported in the ACS. Both housing vintage and type were similar.

Building Envelope

Description

Key Findings

The building envelope comprises the surfaces and insulation that separate conditioned space from the outdoors and is a key determinant of the energy use of any building. Field data collection for single-family homes included extensive characterization of the building envelope, including ceilings, walls, floors, and windows and doors.

Field technicians captured information about exterior surfaces using a variety of techniques. In accessible attics, crawlspaces, and basements, direct observation allowed collection of insulation type and thickness along with other relevant characteristics. With exterior walls, which are typically fully enclosed, field technicians used a combination of infrared thermography and probing around electrical boxes to determine whether a surface was insulated. Probing also often allowed an estimate of the thickness of wall insulation.

Unless otherwise noted, R-values represent only the R-value of the insulation, not of the wall, attic, or floor assembly as a whole.

Key findings for home building envelope include:

- More Northwest homes have attic insulation with R-values greater than 40 in the RBSA II than in RBSA I. However, the RBSA II weighted data show room for improvement—30% of homes have attic insulation with a weighted average R-value less than 11. The lower R-values in RBSA II versus the RBSA I likely reflect differences in methodology. The RBSA II collected data on type, thickness, and completeness of insulation in each attic space rather than estimation of an R-value. The team used these insulation characteristics to calculate a weighted average U-factor and then the R-value.
- The RBSA II data show improvement in wall insulation in Washington, with fewer homes with no wall insulation. Again, the overall shift to lower R-values throughout the region is likely because of differences in methodology. Infrared thermography in the RBSA II study may have allowed more accurate identification of insulated and uninsulated walls, and estimation of the completeness of wall insulation. As with attic insulation, the team used this information to calculate a weighted average U-factor and weighted R-value for the home.

Distribution of Attic Insulation R-Value

Attic insulation data show room for improvement, with **30%** of single-family homes in the Northwest having weighted average R-values less than 11.

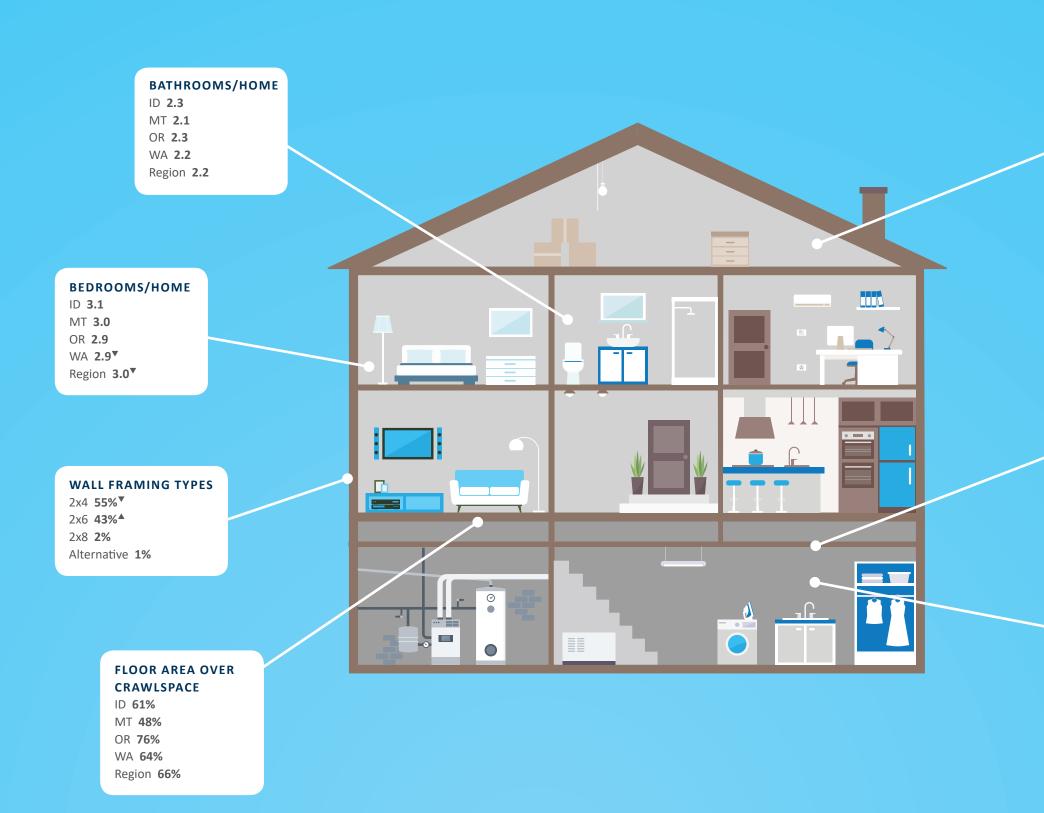

Nearly **10% of homes** in the region have no wall insulation, and another 22% have a weighted average R-value less than R-11 (usually because only some walls have insulation).

Air Leakage

Description

High air leakage in homes squanders energy as conditioned air leaks to outside. It can also lead to occupant discomfort and to moisture-related problems caused by condensation as warm air from inside meets cold surfaces inside walls, attics, or crawlspaces. Where safety protocols allowed, field technicians conducted a blower door test on homes to provide a measure of air leakage.

As prescribed by study protocols, field technicians used a two-point process for conducting the blower door tests, meaning results were measured at two house pressures—roughly 25 pascals and 50 pascals. These data allowed calculation of two commonly used indications of the air tightness of a building: air leakage in cubic feet per minute (CFM) at 50 pascals—denoted CFM50—and air changes per hour at 50 pascals, which is commonly denoted as ACH50. A two-point blower door test allows calculation of an approximation of the slope of the flow curve for each site, which must be assumed when testing at a single pressure. This increased the accuracy of results and allowed a level of quality assurance during testing.

For sites that met eligibility criteria and where practical, visits included a test of airflow across the air handler using the Energy Conservatory's TrueFlow Air Handler Flow Meter. Eligibility requirements included that the primary heating system use electricity as the heat source and that the system configuration allowed a TrueFlow plate to be placed at or near the air handler.

Key findings for homes air tightness include:

Key Findings

- The RBSA II blower door data show less air leakage on average than the previous RBSA homes in Montana, Washington, and the region. The RBSA II weighted regional average of 8.9 ACH50 represents 87% of the RBSA I average. This reduction is likely, in part, from home improvements such as air sealing, installation of high-efficiency sealed combustion furnaces, and window replacement. The addition of new, tighter homes to the housing stock since the previous RBSA also accounts for reduced average air leakage.
- Consistent with RBSA I findings, RBSA II blower door data show higher ACH50 for homes in Oregon and Washington than Idaho and Montana, indicating more air leakage on average in those homes. As expected, air leakage is higher on average with older homes, with average ACH50 ranging from 4.9 for homes built after 2010 to 13.0 for homes built before 1951.
- During TrueFlow air-handler airflow testing, air source heat pumps averaged 280 CFM per ton of heating capacity across the region, and electric forced air furnaces averaged 185. The report Appendix A includes summary tables of TrueFlow results. The RBSA II database shows results for each home, along with other relevant information.

Blower Door Air Tightness (ACH50) by State

RBSA II blower door testing showed **less air leakage** on average than the previous RBSA.

Blower Door Air Tightness (ACH50) by Home Vintage

Air leakage is higher on average with older homes.

HVAC Systems

Description

Code Updates

Key Findings

Data collection included extensive characterization of the heating, cooling, and ventilation equipment in each home. These systems include central equipment such as forced-air furnaces and heat pumps as well as zonal equipment such as baseboard heaters, heating stoves, and ductless mini-split heat pumps. Field technicians also collected information such as the make, model number, capacity, and year of manufacture of heating and cooling equipment where practical. Where year of manufacture was not included on the manufacturer's label, technicians collected serial number data, which often included encoding that allowed the team to determine the year of manufacture after the site visit. Where practical, Cadmus also used post-visit lookups to provide equipment efficiency ratings.

During the working group process, Cadmus collaborated with stakeholders to refine the data collection methods of the RBSA I. One improvement to the data collection, which is reflected in some of the results below, was increased focus on portable and seasonal heating and cooling devices. The field technicians asked residents whether they used these equipment at any point during the year, even if the equipment was stored during the site visit, and they captured relevant information about this equipment if applicable.

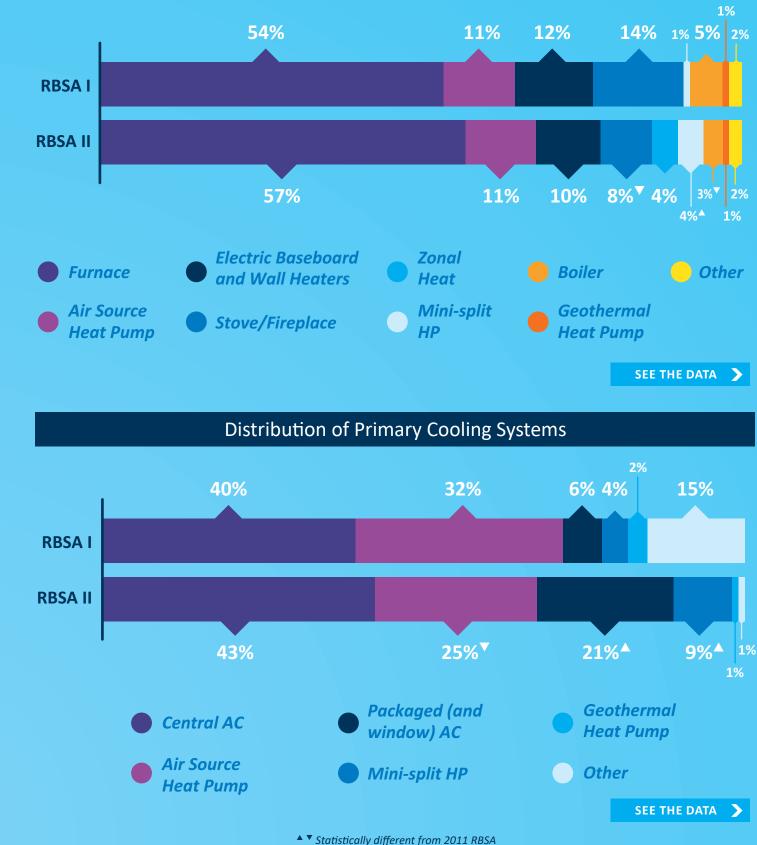

Changes in federal efficiency standards since the last RBSA mandate higher minimum efficiency ratings for some HVAC equipment. For instance, as of May 1, 2013, the minimum annual fuel utilization efficiency (AFUE) of nonweatherized gas furnaces for stick-built homes increased from 78 to 80. As of January 1, 2015, the minimum seasonal energy efficiency ratio (SEER) of split system heat pumps increased from 13 to 14, and the minimum heating seasonal performance factor (HSPF) increased from 7.7 to 8.2.

Key findings for HVAC include:

- Primary heating equipment remained much the same in RBSA II as in the previous RBSA, with two notable changes. First, use of heating stoves and fireplaces as the primary heating system decreased from 14% to 8%, and second, use of mini-split heat pumps increased from 1% to 4%.
- For electrically heated homes, the percentage of households using mini-split heat pumps as their primary heat source increased from 5% in RBSA I to 12% in RBSA II.
- The percentage of homes using some type of mechanical cooling increased from 42% to 57%. An increase in the use or identification of portable air conditioners, packaged air conditioners (window units), and ductless heat pumps appears to account for this difference.

Distribution of Primary Heating Systems

Distribution of primary heating and cooling systems was similar to the previous RBSA. The only notable changes included a **decrease in heating stoves** and fireplaces for primary heat and an increase in mini-split heat pumps.

Distribution of Primary Heating Fuel Type by State

Gas fuel increased from 49% to 56%. Other alternative fuel sources declined.

Lighting

efficient light bulbs.

Key findings for homes lighting include:

proportional share.

in 2% of homes.

Lighting data collection is a highly involved process, encompassing lighting inside and outside the residence as well as equipment kept in storage. Cadmus conducted a comprehensive lighting walk-through that captured details about lighting in every room accessible to the field technician. These details include lamp type, style, wattage, quantity, control, and location. In addition to bulbs currently installed, field technicians identified and recorded bulbs in storage.

To ensure all relevant data were collected, field technicians performed a systematic walk-through of the home, documenting control types, fixtures, lamp attributes, and quantities. They began the process by asking the resident about spare bulbs and recording bulb type and quantities. Identifying the type of bulb can be difficult due to accessibility or safety issues and the fact that many bulbs today look like incandescent but are in fact something different, such as a halogen. Where field technicians could not accurately assess the bulb type, they noted it as unknown.

Collecting information about LEDs and connected lighting, or lighting with an element of connectivity or intelligence, was new to this RBSA.

The Energy Independence and Security Act of 2007 was phased in beginning in 2012. This standard impacted many lamps that would have been targets

Appliances

Description

Code Updates

Key Findings

The appliance data collection identified and characterized appliances in each home, including kitchen and laundry appliances. This section includes

distribution of appliances by state and region, specific characteristics such as age and size, and appliance configurations such as door position for refrigerators. In many instances, Cadmus identified characteristic data such as age, efficiency, and size after the site visit through a combination of databases and other secondary sources.

For the first time, the RBSA II collected information about connected appliances (that is, appliances that are connected to the homes' Wi-Fi). In addition to identifying the presence of clothes dryers and fuel type, the RBSA II captured more information regarding clothes dryer configurations and other details (included in Appendix A).

Federal energy efficiency standards can have a significant impact on appliance stock and efficiencies in particular. There have been a few federal efficiency standard changes since the previous RBSA. Appliances impacted by federal efficiency changes include the following equipment:

- Refrigerators and freezers (effective 2014)
- Clothes washers and dryers (effective 2015)
- Dehumidifiers (effective 2012)
 - Dishwashers (effective 2013)

Key findings for appliances include:

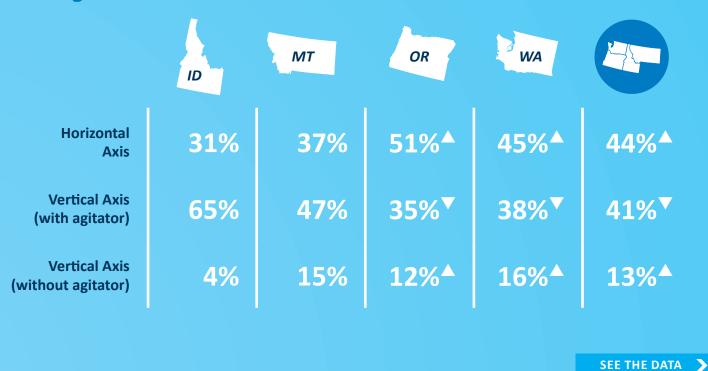

- Appliance distributions, types, and efficiencies show some shift since the last RBSA. For instance, the distribution of clothes washer and refrigerator efficiencies and configurations changed.
- The average appliance age was 10 years, with 32% of dryers and 28% of dishwashers beyond their useful life. Useful life is based on Regional Technical Forum assumptions and ranges from 12 to 22 years, depending on the appliance.
- There were significant shifts in refrigerator configuration types: refrigerators with top freezers declined the most since the previous RBSA, and side-by-side refrigerators with bottom freezers increased the most. In general, side-by-side configuration refrigerators have been shown to consume more energy than single-door units when all else is equal.

Average Number of Appliances per Home

Dishwasher Dryer Freezer Refrigerator Washer

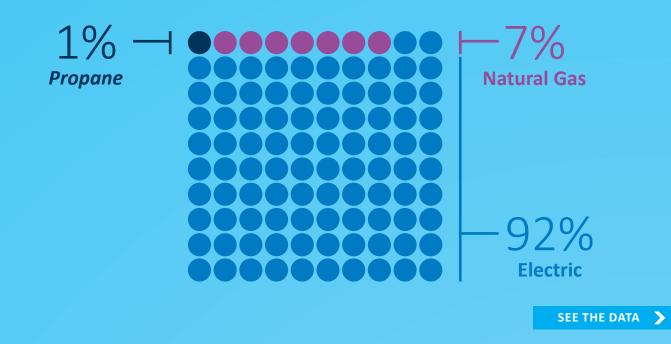

Horizontal and vertical axis (without agitator) washers increased from a combined share of 39% to 57% across the region.

Distribution of Clothes Washer Types

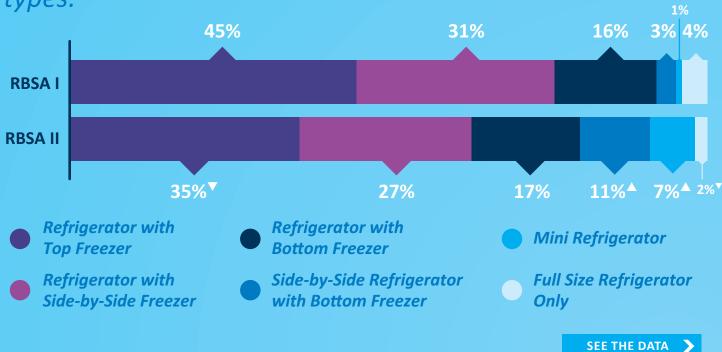

Distribution of Clothes Dryer Fuel Types

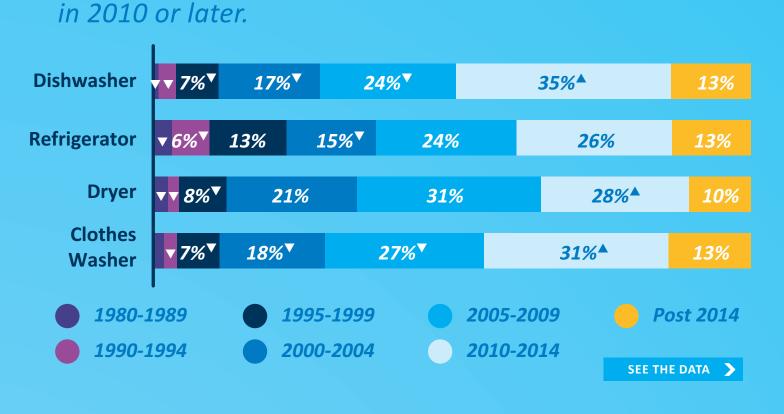

The RBSA II found **92%** of dryers are electric, followed by natural gas (7%) and propane (1%).

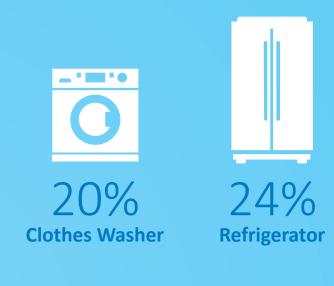

Distribution of Refrigerators by Type

There were significant shifts in refrigerator configuration types.

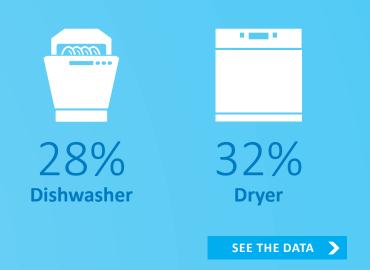

A substantial proportion of appliances are past their useful life.

Appliance Age

Roughly 38% to 50% of appliances were manufactured

Proportion of Equipment Past Effective Useful Life

Water End-Uses

Field technicians identified and characterized water heaters in each home. Specifically, they collected information regarding the water heater type,

size, fuel, make, model, input capacity, and location. Location is especially important for heat pump water heaters (HPWHs) because the location may affect not only how much energy is required to heat water, but also how much energy is required to heat and cool the home. For example, the

HPWH will have less impact on heating and cooling the farther it is from

the thermostat and the more thermal buffers that exist between it and the thermostat. However, HPWH efficiency will decline in winter if the water heater is located outside of the thermal boundary. The RBSA II did not directly capture the distances and thermal buffers, but field technicians

noted where electric water heaters were located by room type. Collected data also included additional information such as ceiling height near the water heater and proximity to exterior walls for running vent ducts. This may help programs identify how many electric water heaters can be easily

Field technicians also conducted a thorough walk-through for showerheads and faucet aerators. For these end uses, technicians captured the rated

Federal energy efficiency standards can have a significant impact on water

heater efficiencies. New federal efficiency changes for water heaters went

• There were a few statistically significant shifts with water heaters,

including water heater fuel type. Homes with gas water heaters

Saturation share of instantaneous water heaters increased from 3%

• Distribution of electric water heater location by space heating fuel

type shows 41% are located in the main house, 30% in the basement, 23% in the garage, and the remaining 6% in other locations around

flowrate (if available) and measured flowrate using predetermined procedures and equipment. The end uses were classified as primary,

Average Number of Showerheads and Faucets Per Home

Single Family Homes have 2.5 bathroom sinks, **0.7** standalone showers, and **0.8** shower and bath combo units

On average, homes have **1.1** kitchen sinks

This page intentionally left blank.

Electronics

Description

Key Findings

The electronics walk-through identified and characterized electronics in each home. Equipment captured included a range of electronic devices from televisions to computers. Field technicians did not include portable devices such as iPads and phones because of their general mobility. This section includes distribution of electronics by state and region, along with specific characteristics such as size, type, and usage. In some instances, Cadmus identified characteristic data such as efficiency and size after the site visit by searching a third-party database, manufacturer data sheets, or other online resources.

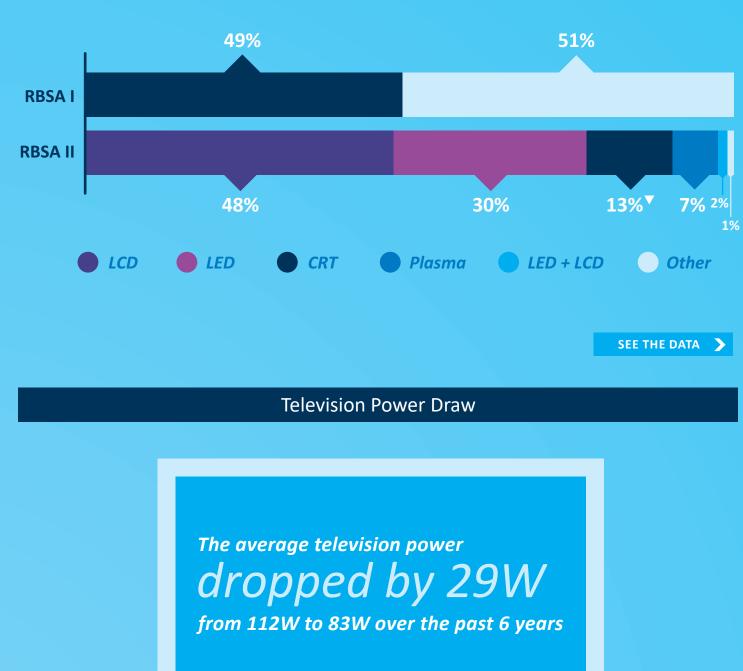

The walk-through also included capturing information regarding power strips and auxiliary items that may be plugged into them. Field technicians measured the television wattage whenever possible, using a plug-through power meter, and recorded the presence of television peripherals such as Roku, Fire Stick, and Apple TV devices. Technicians asked participants about usage patterns (e.g., how many hours per day each television is typically on).

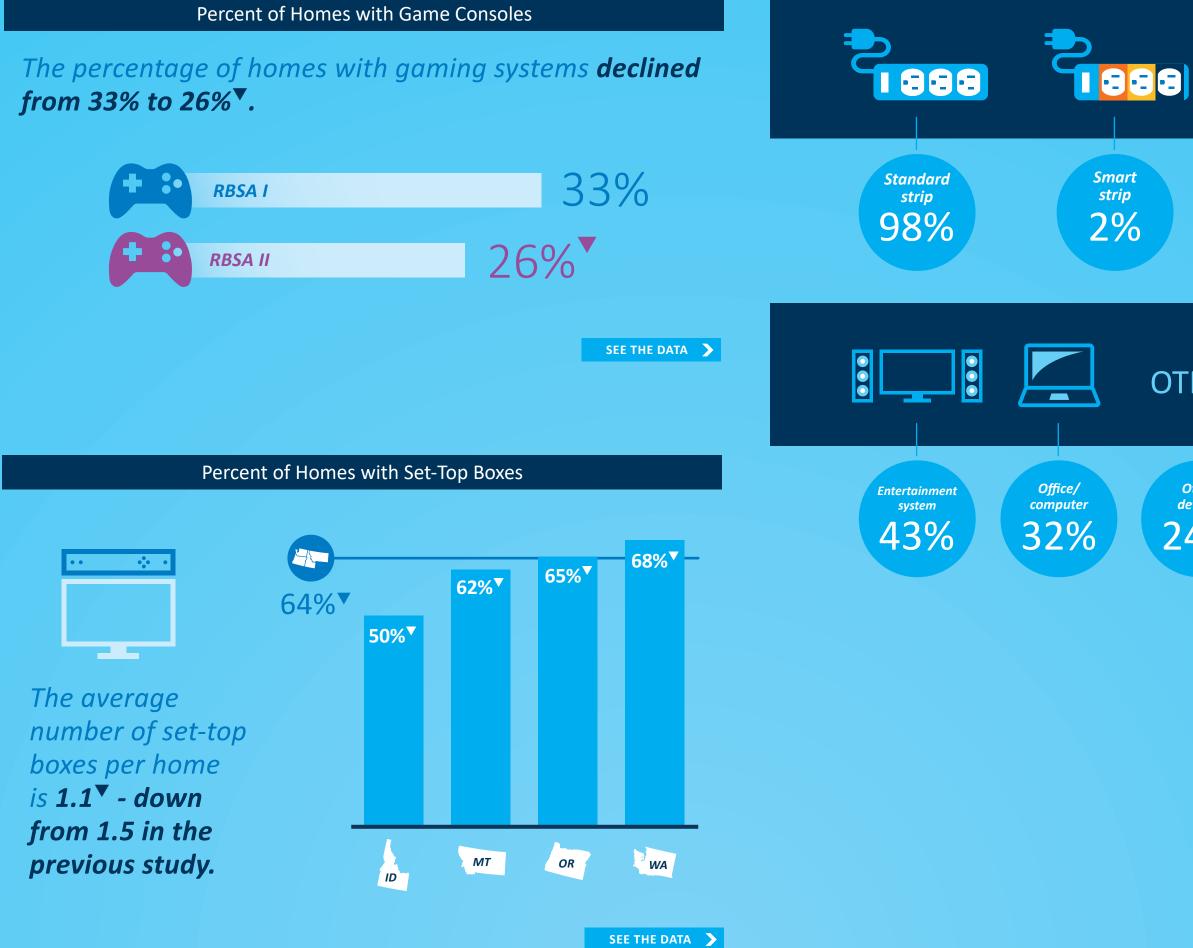

Key electronic findings include:

- There have been many advancements in television technology since the last RBSA. Cathode ray tube televisions represented about half of all televisions found in homes since the last RBSA, whereas currently they represent only 13% of televisions, with LED and LCD televisions representing over three-quarters of what is currently installed in homes.
- Households now contain fewer televisions (2.3 to 2.1 per household), and the percentage of televisions present by room type declined or stayed the same for most room types except bedrooms and living rooms. The percentage of bedrooms and living rooms containing a television increased from 25% and 29% in RBSA I to 37% and 35% today.
- Set-top boxes and audio systems are declining in numbers. The number of homes with set-top boxes declined from 81% in RBSA I to 64% in RBSA II. Audio systems per home saw a significant decline from approximately two per home to fewer than one per home (0.8) on average. These changes are likely due to the popularity of web-enabled televisions and streaming services such as Netflix and Spotify.

Distribution of Television Screen Types

Over three-quarters of televisions now use LED or LCD technology

Key Findings

Energy Benchmarking

Similar to the previous RBSA, the RBSA II provides an opportunity to calculate energy-use intensity (EUI) profiles. Cadmus conducted the RBSA II billing analysis using procedures and methods similar to those used for the previous study to allow for direct comparison of the results. Cadmus requested 24 months of electric and gas billing data for all 1,100 singlefamily participants. However, the team ultimately removed 121 sites for several reasons: the utilities did not provide billing information (most common), inconsistencies in data collection such as multiple readings on the same date or missing reads, or anomalies in the data such as lengthy vacancies or apparently erroneous readings. In the end, the analysis included billing data for 979 electric and 479 gas participants.

Key energy usage findings include:

- Average electric and gas usage per home remained relatively unchanged across the region from the last RBSA. There was a noticeable decline in other fuel use in Oregon and Washington.
- Annual electric usage per square foot remained the same for Oregon and Washington, decreased by 1.5 kWh per square foot for Idaho, and increased by 1.8 for Montana.
- Gas EUI decreased in Oregon and Washington but remained the same in Idaho and Montana. EUI for other fuel sources declined significantly in every state except for Idaho.
- Higher electric EUIs were largely driven by whether a home had electric heating and electric water heating. Homes with large conditioned areas had lower EUIs. Variables such as efficient lighting and percentage of mechanical cooling did not vary much across quartiles.

| | ID | МТ |
|---|------|------|
| Electric EUI per Home (kWh/sq.ft) | 7.4 | 8.24 |
| Gas EUI per Home (therm/sq.ft) | 0.4 | 0.5 |
| Other Fuel EUI per Home (kBtu/sq.ft) | 4.6▼ | 7.1 |

Conservation, Purchases, and **Miscellaneous** Loads

Description

Key Findings

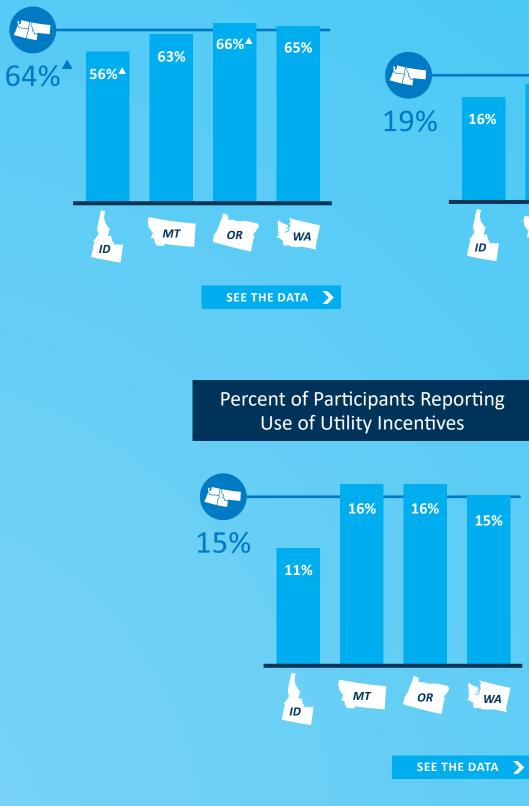

As part of the recruitment process, recruitment specialists asked a series of questions related to household purchases and energy efficiency awareness. Specifically, specialists inquired if households had participated in rebate programs and, if so, which ones and what the participant purchased. The recruitment specialists also asked if participants received any federal, state, or local tax credits, or if they completed a home energy assessment in the past two years. Finally, specialists asked participants whether they or a landlord pay their gas and electrical bills and whether they receive financial assistance for their utility bills (and if so, what portion of the bill is covered by financial assistance).

Data collection also captured information about miscellaneous and uncommon loads such as electric vehicle chargers, solar panels, smart home devices, well pumps, and pool and sauna equipment.

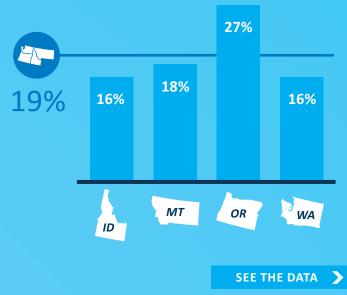

Key conservation, awareness, and miscellaneous findings include:

- A higher percentage of participants reported implementing conservation improvements without utility incentives in the past two years in this study compared to the previous RBSA (64% and 48%, respectively). This upward trend was true for all states except for Montana, which remained about the same. Out of the participants reporting some sort of energy efficient home improvement, roughly the same percentage as the last RBSA reported receiving an incentive from their utility (approximately 15% for the region).
- Approximately 3% of homes have solar panels, with Oregon and Washington having the most. Field technicians identified a small number of homes, nine in total, with electric vehicles present.
- Technicians also asked homeowners if they use or access any type of smart home device (such as a smart speaker like Google Home). Just over 9% of homeowners responded to having such devices, with Montana having the highest percentage of smart device users (11%).

Percent of Participants Reporting They Implemented Some Kind of Self-Funded Conservation Improvement

RESIDENTIAL BUILDING STOCK ASSESSMENT^{Appendix A:} Report Tables

Introduction

This appendix presents findings for single-family homes based on data collected for the core RBSA II study (funded by NEEA) and on data collected for three oversamples funded by the Bonneville Power Administration, Seattle City Light, and the Snohomish Public Utility District. Cadmus developed and applied sampling weights to ensure that all single-family home observations were weighted proportionally to the segment of the population represented by the sample; see the Database User Manual for a description of the weighting methods and procedures.

Where possible, Cadmus benchmarked the findings of the RBSA II against the findings presented in the RBSA I. Statistically significant differences between the two reports are denoted by either a \blacktriangle or \triangledown symbol, to indicate whether the RBSA II value is higher or lower than the value in the RBSA I study. This appendix identifies which table in the previous study was used to draw conclusions about each statistically significant difference.

New tables and categories presented in this document that do not have a corollary in the RBSA I study do not have symbols indicating statistically significant increases or decreases from RBSA I, though statistically significant differences may exist. Without a comparable table in the RBSA I report, statistical testing could not be performed.

Table 197. PERCENTAGE OF ELECTRICALLY HEATED HOMES REPORTING A HEATING SETBACK BY STATE(Compare to Table B-16 in 2011 RBSA)

| State | Homes Reporting Heating Setback | | | | | | |
|--------|---------------------------------|-------|-----|--|--|--|--|
| State | % | EB | n | | | | |
| ID | 34.7% | 16.1% | 27 | | | | |
| MT | 48.6% | 24.3% | 19 | | | | |
| OR | 43.4% | 11.9% | 114 | | | | |
| WA | 51.1%▼ | 7.4% | 269 | | | | |
| Region | 46.5%▼ | 5.7% | 429 | | | | |

Table 198. AVERAGE WEATHER NORMALIZED KWH PER HOME BY STATE, ELECTRICALLY HEATED HOMES(Compare to Table B-17 in 2011 RBSA)

| State | kWh p | er Home | |
|--------|------------|---------|-----|
| State | Mean | SE | n |
| ID | 16,855.5 | 1,861.3 | 22 |
| MT | 15,666.4 | 1,819.1 | 18 |
| OR | 14,316.3 | 980.7 | 101 |
| WA | 16,198.9 🔻 | 800.0 | 233 |
| Region | 15,688.9▼ | 568.4 | 374 |

Table 199. DISTRIBUTION OF PRIMARY HEATING SYSTEMS, ELECTRICALLY HEATED HOMES

| | Primary H | eating Syst | tems |
|-------------------------------------|-----------|-------------|------|
| Heating System Type | % | EB | n |
| Air Source Heat Pump | 28.7% | 4.9% | 131 |
| Boiler | 0.5% | 0.7% | 3 |
| Electric Baseboard and Wall Heaters | 29.6% | 5.0% | 115 |
| Furnace | 10.0% | 3.4% | 45 |
| GeoThermal Heat Pump | 1.8% | 1.3% | 9 |
| Mini-split HP | 11.9% | 3.2% | 52 |
| Other Zonal Heat | 8.8% | 3.0% | 57 |
| Plug-In Heaters | 8.5% | 3.6% | 28 |
| Stove/Fireplace | 0.1% | 0.5% | 1 |
| Total | 100.0% | 0.0% | 429 |
